## **ISGMR** measurement in Xe isotope with CAT-M

Thursday, 19 August 2021 16:15 (15 minutes)

The nuclear matter compressibility  $(K_{\tau})$  is an important physical quantity that can directly determine a part of the equation of state of nuclear matter. In order to determine  $K_{\tau}$  with high accuracy, it is indispensable to determine the compressibility of many nuclei  $(K_{\rm A})$ . We have been developing an active target CAT-M for the purpose of systematic measurement of an isoscalar giant monopole resonance (ISGMR).

In this study, we performed a ISGMR measurement using the  $^{136}$ Xe (d, d') reaction as the first measurement of systematic measurements with the Xe isotope. A dipole magnet was newly introduced into CAT-M for eliminate the delta rays by high intensity heavy ion beam in the experiment. Moreover a Mini TPC that has  $10 \times 30 \times 30$ mm<sup>3</sup> active volume, was introduced for measure the beam angle. We will report the outline of the experiment.
