Measurement of ${}^{130}{ m Sn}(d,p)$ and ${}^{130}{ m Te}(d,p)$ reactions with TiNA for Neutron Capture Rate in r-process Nucleosynthesis

Saturday, 20 August 2022 13:30 (15 minutes)

Neutron capture rate on neutron-rich nuclei is one of the most uncertain nuclear physics parameters to understand the r-process nucleosynthesis in the universe. According to the network simulation of the nucleosynthesis, the neutron capture on ¹³⁰Sn significantly affects the final abundances of the r-process. To reduce the uncertainty, we performed the experiment to study the neutron capture rate of ¹³⁰Sn using the surrogate ratio method at the BigRIPS-OEDO beamline in RIKEN's RIBF. In this experiment, we measured ¹³⁰Sn(d, p) and ¹³⁰Te(d, p) reactions separately in inverse kinematics to determine the ratio of the gamma emission probabilities from the respective unbound states. The protons recoiled from the CD₂ solid target were detected by a recoil particle detector array, TiNA.

The present status of the analysis will be discussed.
