

Study on LaBr₃(Ce) gamma-ray detectors by using Geant4 simulation

Monday, 26 August 2019 15:40 (15 minutes)

The gamma-ray detector array composed of 24 LaBr₃(Ce) scintillators is now in preparation for the decay spectroscopy with the fast-timing gamma-ray measurements by the Center for Extreme Nuclear Matters (CENuM) in Korea. Accordingly, the simulation based on the Geant4 framework has been performed for various purposes.

The encapsulated LaBr₃(Ce) crystal with a size of 1.5-inch diameter was applied to the simulation to reproduce the energy spectra from the experiments with several radiation sources. Moreover, the self-radioactivity of La-138 contained in the crystal was considered to reproduce the background energy spectrum.

From our work on the simulation, the primary goals are as followings: reproducing the expected energy spectra from the specific beta-decay experiments, designing the detector configuration, and the efficiency calculations. In this presentation, we introduce our recent results from the Geant4 simulation of the LaBr₃(Ce) gamma-ray detectors.
